# Lecture V Learning Objectives

☐ Review the characteristics and elements of Agent Oriented Programming and Object Oriented Programming

Assignment Project Exam Help

☐ Review the difference between an Agent and an Object

<https://eduassistpro.github.io/>

☐ Understand the elements and characteristics of an Agent

Add WeChat edu\_assist\_pro

☐ Understand the different Agent Programming Language

☐ Understand how Belief Management occurs on a MAS and the temporality of Beliefs

☐ Understand and identify the different Commitment States

# Agent Oriented Programming

Introduced in 1993 by Yoav Shoham (Stanford).

Based on the idea of programming agents as mental entities.

A complete AOP System includes three primary components:

- a **restricted formal** language with its own syntax and semantics for describing mental states. <https://eduassistpro.github.io/>
- an **interpreted programming language** in which to define and program agents, with primitive services (such as request and inform).
- an **"agentifier"** (method), converting neutral devices into programmable agents.

Shoham illustrated this through a prototype AOP language, Agent-0.

# Agents Vs Objects

- Silva defines an agent as “an extension of an object with additional features”
- Extends the definition of state and behaviour
- Agents have the “freedom” to control and change their behaviors.
- Agents are autonomous. <https://eduassistpro.github.io/>
- Methods are made available for invocation when desired;
- Agents do not invoke methods but make “ ”
- Objects have nothing to say about differing deductive models like reactive or exhibit social abilities
- Agents are each considered to have their “*own thread of control*”.
- In standard object systems there is merely one thread

# Active vs Passive Objects

- Objects do not require external stimuli to carry out their jobs.
- Agents active elements and passive ones.
- Active Objects blur the line between active and passive ones.
- Active objects have their own thread of control and can in some senses be considered autonomous.
- They exhibit some behaviours without actually being operated upon.

# OOP and AOP, a comparison

## OOP

1. abstract class
2. Class
3. member variable
4. Method
5. collaboration (uses)
6. composition (has)
7. inheritance (is)
8. instantiation
9. polymorphism

## AOP

1. generic role in specific role
2. led belief
3. Add WeChat edu\_assist\_pro
4. Negotiation
5. holonic agents
6. role multiplicity
7. domain specific role + individual knowledge
8. service matchmaking

# Executing AF-APL

- AF-APL is executed on a purpose-built agent interpreter.
  - **The agent class is loaded into the interpreter when the agent is created.**
  - **Control functions can be used to suspend, resume, and terminate the operation of the agent.**
- The interpreter processes the environment (beliefs) and makes decisions about how to act (commitments).
- Two problems arise from this:
  - **How to ensure that the model of the environment is up-to-date?**
  - **How to make the decision about how and when to act?**
- These problems are known as the belief management and commitment management problems, respectively.

Belief Management = Belief Update + Belief Query

- Belief Update.

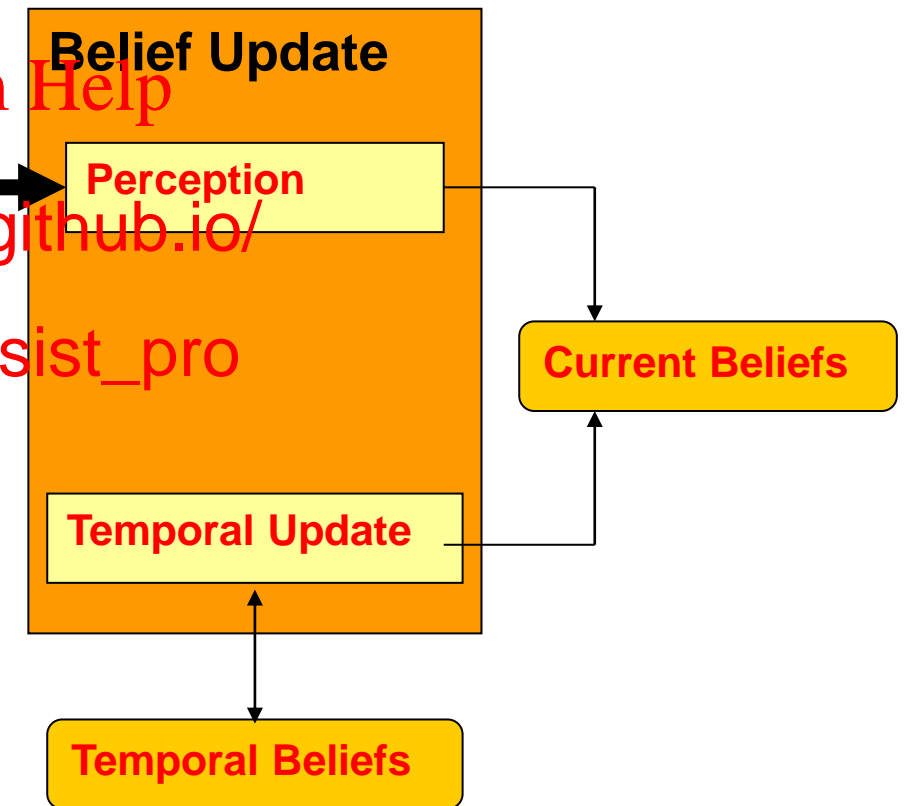

- Dynamic Environment  
Transitory beliefs
- Persistence can be supported through temporal operators  
(e.g. ALWAYS, NEXT)
- Belief update = gathering perceptions + updating the temporal beliefs.

# Belief Management

## ■ Belief Query.

- Beliefs = Facts + Implications (Belief Rules).
- Resolution-based reasoning on current beliefs

# Representing Beliefs in AF-APL

- AF-APL supports three forms of belief:
  - **Current Beliefs.** Beliefs that are true at the current time point.
  - **Temporal Beliefs.** Beliefs that persist over more than one time point.
  - **Belief Rules.** Rules that define inferences that can be made on the current beliefs.
- In AF-APL a belief is represented within a BELIEF operator:
  - **BELIEF(happy(rem))** – a belief that rem is happy
  - **BELIEF(likes(?person, beer))** – a belief that some person likes beer
  - **BELIEF(bid(fred, 50))** – a belief that fred has bid 50
- These beliefs are current beliefs and apply only at the current time point. As a consequence, they are wiped at the start of each iteration of the AF-APL interpreter.

Assignment Project Exam Help

<https://eduassistpro.github.io/>

**Order structure** enclosed  
Add WeChat edu\_assist\_pro

# Temporal Beliefs

- **ALWAYS** – the belief is a current belief and will persist until the temporal belief is dropped.

**ALWAYS(BELIEF(happy(greg)))** – always believe that greg is happy

- **UNTIL** – the belief is a will persist until either the temporal belief is dropped or condition is satisfied.

**UNTIL(BELIEF(drinking(wine, greg)))** **EF(not BELIEF(available(wine)))**

– believe that greg is drinking  
do not believe that there is wine available.

- **NEXT** – the belief will be a current belief at the next time point.

**NEXT(BELIEF(finished(wine)))** – at the next time point belief that the wine is finished.

- These beliefs are maintained until they are explicitly dropped.

# Belief Rules

- Belief Rules define inferences that can be made over the current beliefs of the agent.

Assignment Project Exam Help

- They take the form: <https://eduassistpro.github.io/>

**BELIEF(likes(?food)) & BELIEF(wants(?food)) =>**  
Add WeChat edu\_assist\_pro

**BELIEF(has(rem, icecream)) => BELIEF(happy(rem))**
